N Management under No-till on the Canadian Prairies

 Majority of N is applied in the soil at time of seeding using a one-pass seeding and fertilizing system

Challenge with Post-Emergent-N (PE-N) Management

It is very difficult to improve on the no-till one-pass seeding and fertilizing system because of its proven and recognized high efficiency.

Why the interest with Post Emergent N Applications in Western Canada?

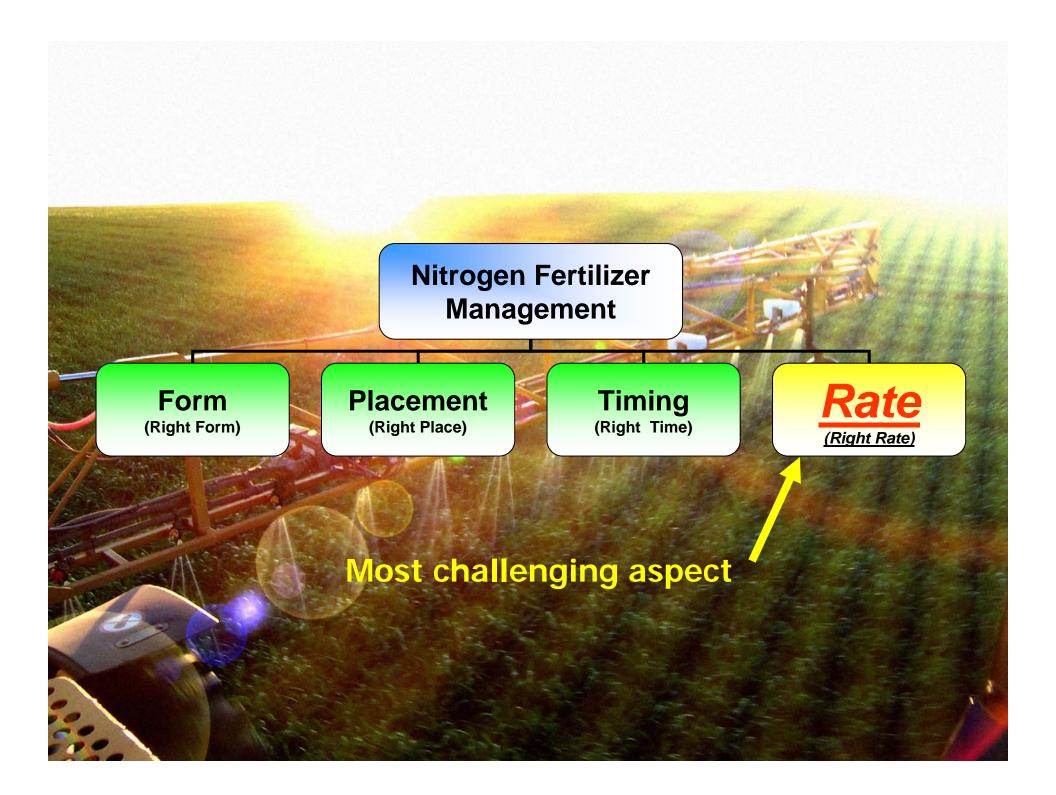

- Reduce volume of fertilizer material required at seeding.
 Potentially a better risk management tool for nitrogen fertilizer application in dryland cropping systems.
- Ability to apply N closer to the time of maximum crop uptake.

Where are we at with this concept-Part 1 (2001-03)?

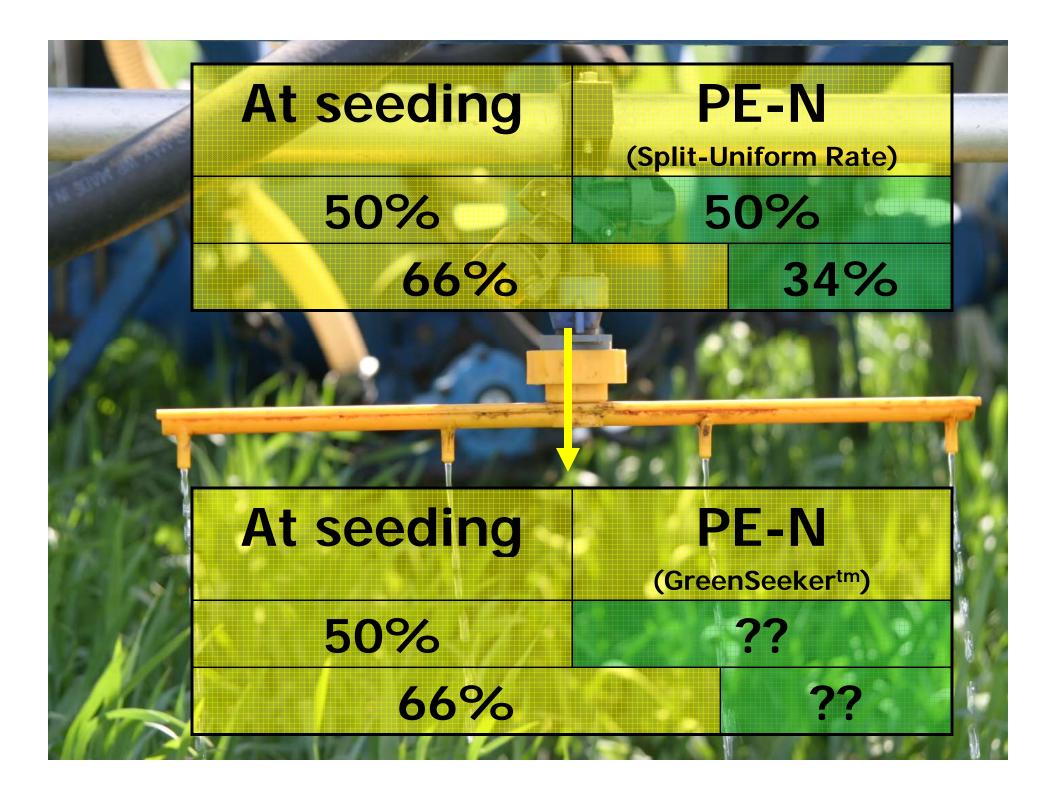

- Test Crop: Spring wheat and canola
- PE-N application: 1, 10, 20 & 30 days after planting (UAN-surface dribble) vs all at planting
 - Biggest risk is delay in receiving significant rainfall after application.
 - Coulter injection reduces but does eliminate the risks associated with PE-N
 - Need to consider some N at time of seeding as a way to control risks

Where are we at with this concept-Part 2 (2004-06)?

- Test Crops: Spring wheat and Canola
- Adding some N at seeding significantly reduces the risks of post-emergent N applications.
 - Recommend a minimum of 50% of total fertilizer N requirements as starter N
 - Spring wheat: PE-N up to 5-6 leaf stage Canola: PE-N up to appearance of first flowers

Objective

To validate the application algorithms developed for the GreenSeekertm sensor in cereals and canola using small plots and to continue with the evaluation of the merits of PE-N.

List of Crops

- Durum wheat
- Spring wheat
- Winter wheat
- Malting Barley
- Oat
- Canola

List of Treatments

- 1. Check (no nitrogen)
- 2. N rich (NR)
- 3. Farmer Practice (FP)
- 4. 66% of FP (RR)
- 5. 50% at seeding + 50% PE-N
- 6. 66% at seeding + 34% PE-N
- 7. 50% at seeding + PE-N with GS
- 8. 66% at seeding + PE-N with GS

Timing of PE-N

- Cereals: ~ 6 leaf stage
- Canola: mid-bolting stage

Total N Applied for the Various Treatments in 2008 (kg N/ha)

Summary to Date

- PE-N Split N treatments performed equally as all N applied at seeding in all crops.
- Use of GStm Algorithms resulted in less N applied and similar yields for durum, spring wheat, oat and barley.
- Use of GStm Algorithms resulted in less N applied and lower yields in canola.
- Challenge of choosing an appropriate N Rate.
- Challenge of improving over the one-pass seeding and fertilizing system.

Other Potential Uses of the GreenSeeker Optical Sensor

Tool for assessing yield potential

Where do we go from here?

- Need to bring the technology to the farm gate
- Need to address the logistics of using this technology at the farm gate
- Need to draw from more on-farm experience to enhance the potential of optical sensors
- Need to expand the applications of optical sensors as decision making tools to other situations given its ability to predict yield potential
